

Jupyter and IPython

The Jupyter package is designed to facilitate interactive computing, especially for code editing, mathematical expressions, plots, code/data visualization, and parallel computing. The IPython kernel is included in the package. Jupyter supports many alternative kernels, also known as language interpreters. See details below.

The instructions below describe how to start the browser-based **JupyterLab**, the **IPython shell**, and **Jupyter QtConsole** on the Cheyenne system and the Casper data analysis and visualization nodes.

For additional information, see [JupyterHub at NCAR](#) and the [Jupyter documentation](#).

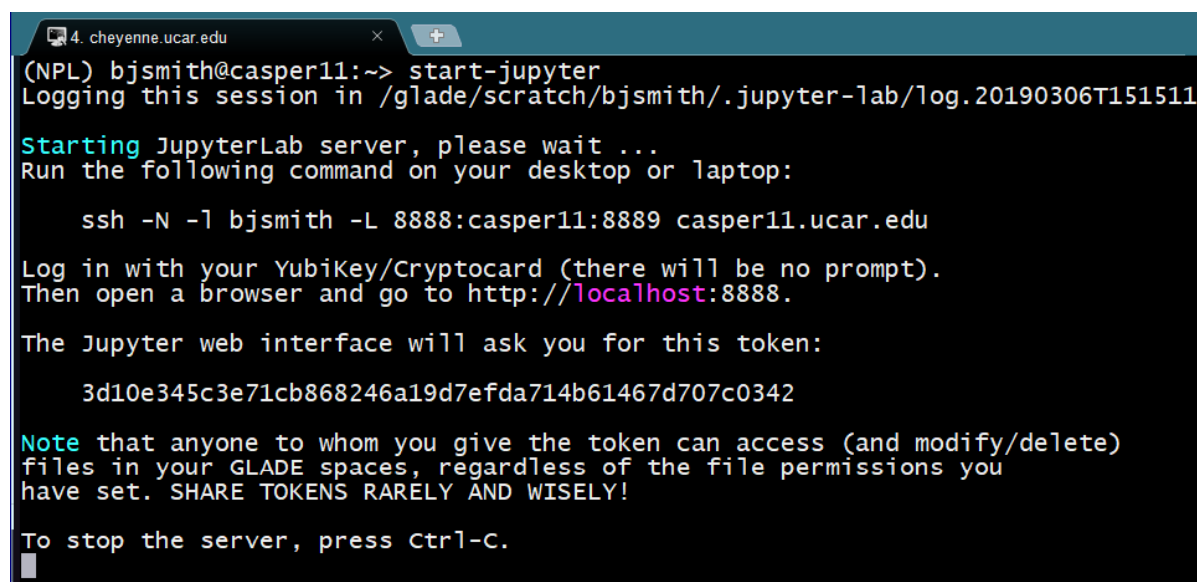

Page contents

- [Using alternative language kernels](#)

Starting JupyterLab

- Start an interactive job using the **qinteractive** command. (Alternative: Start the job on Casper using **execcasper** if it requires GPUs or more memory than is available on Cheyenne.)
- Load the **ncarenv** and **python** modules.
- Run the **ncar_pylib** command to load the NCAR Python Library virtual environment.
- Run the **start-jupyter** command. (The older Notebook interface is still available using the **start-notebook** command.)

The output includes instructions like those shown in the image just below. Including the **-N** after the **ssh** command establishes the tunneling that allows you to use JupyterLab in your local browser. It also prevents you from actually opening a second ssh session. If you prefer to have a second session open, omit the **-N**. When you close that session, you will be closing your browser connection to JupyterLab.

```
(NPL) bjsmith@casper11:~> start-jupyter
Logging this session in /glade/scratch/bjsmith/.jupyter-lab/log.20190306T151511

starting JupyterLab server, please wait ...
Run the following command on your desktop or laptop:

    ssh -N -l bjsmith -L 8888:casper11:8889 casper11.ucar.edu

Log in with your YubiKey/Cryptocard (there will be no prompt).
Then open a browser and go to http://localhost:8888.

The Jupyter web interface will ask you for this token:

    3d10e345c3e71cb868246a19d7efda714b61467d707c0342

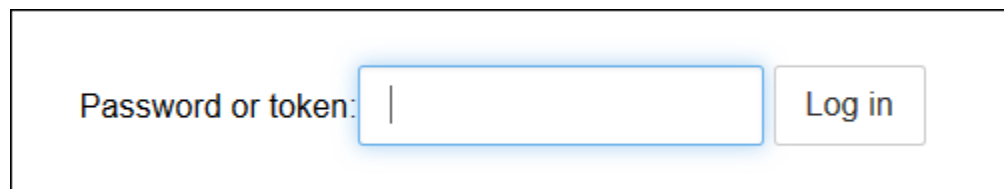

Note that anyone to whom you give the token can access (and modify/delete)
files in your GLADE spaces, regardless of the file permissions you
have set. SHARE TOKENS RARELY AND WISELY!

To stop the server, press Ctrl-C.
```

On your local computer, run the **ssh** command as instructed.

The session will appear to hang after you log in. At that point, start **http://localhost:nnnn** in your browser. (The port numbers may be different from those in the output example above.)

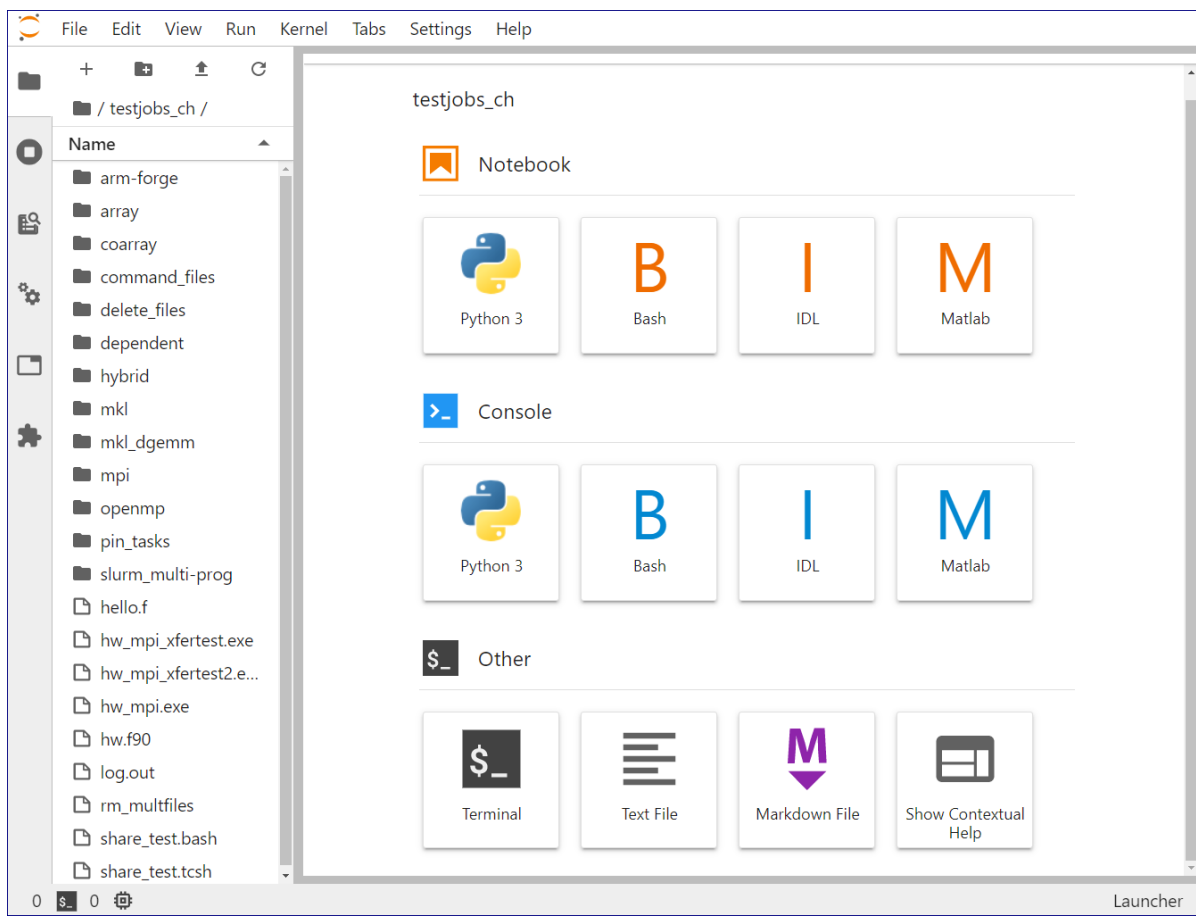

JupyterLab will request a password or "token," which is a long string as shown in the output above that you can copy and paste from your terminal.

Password or token:

Log in

Your browser will open the JupyterLab web interface after you log in with the token.

Starting IPython shell

- Start an interactive job using the **qinteractive** command. (Alternative: Start the job on Casper using **execcasper** if it requires GPUs or more memory than is available on Cheyenne.)
- Load the **ncarenv** and **python** modules.
- Run the **ncar_pylib** command to load the NCAR Python Library virtual environment.
- Run the **ipython** command to start the shell.

Starting Jupyter QtConsole

- Log in with X tunneling (using the ssh **-X** option).
- Start an interactive job using the **qinteractive** command. (Alternative: Start the job on Casper using **execcasper** if it requires GPUs or more memory than is available on Cheyenne.)
- Load the **ncarenv** and **python** modules.
- Run the **ncar_pylib** command to load the NCAR Python Library virtual environment.
- Run the **jupyter qtconsole** command to start the console.

Using alternative language kernels

Jupyter supports multiple language interpreters (known as "kernels"). The Python interpreter is loaded by default as the language kernel when using Jupyter, but you can specify use of another kernel when invoking a particular command. To see a list of installed language kernels, run this command:

```
jupyter kernelspec list
```

To use a kernel, specify it by name when invoking a command. For example, to use the R 3.4.0 interpreter on Cheyenne in the Jupyter QtConsole, enter the following:

```
jupyter qtconsole --kernel=r-3.4
```

The console will load with the R command line interpreter active.

If you need a language kernel that has not been installed, you can install it yourself in your local directory or [contact the NCAR Research Computing help desk](#) to have it added in the system library.
